1.0 General Information

1.1 Product

ChamClad 6-in. wide, V-groove PVC Exterior Panel

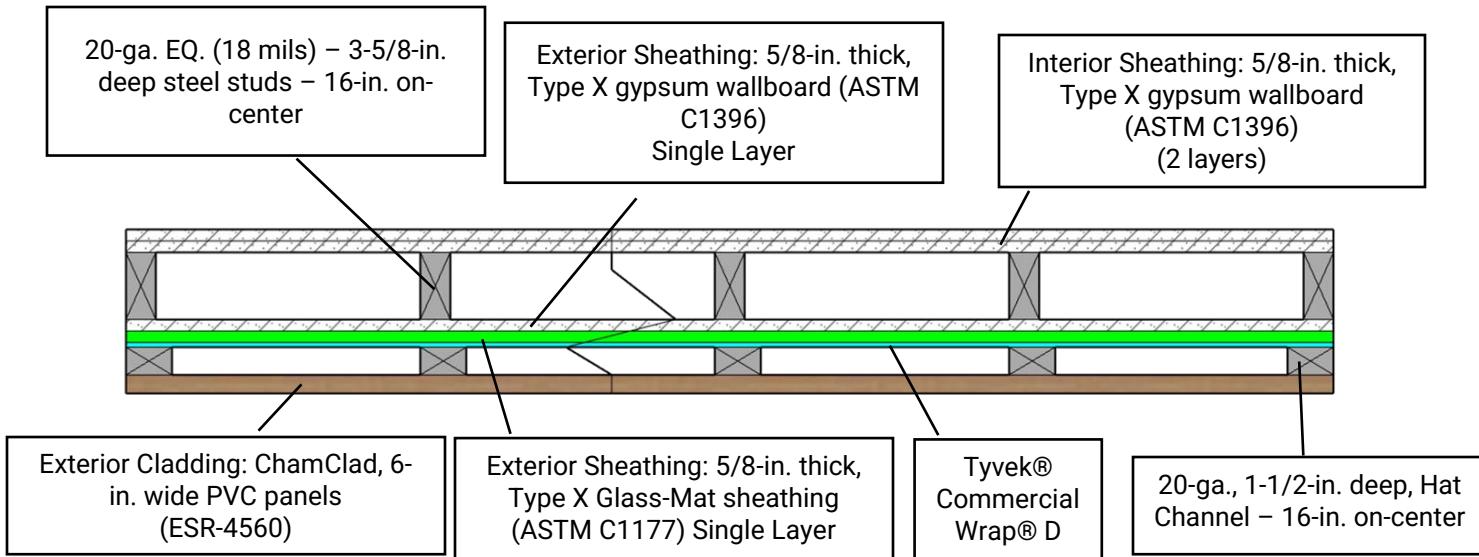

1.2 Project Summary

ICC NTA, LLC was contracted by ChamClad to evaluate ChamClad 6-in. wide, V-groove PVC Exterior Panel in accordance with ASTM E119. Results obtained are tested values and were secured by using the designated test method(s). Testing was conducted at ICC NTA's facility in Bryan, Texas.

1.3 Product Description

The wall system(s) described in this report consisted of ChamClad 6-in. wide, V-groove PVC Exterior Panels installed over a base wall constructed per UL Design No. U419.

The 6-in. wide, V-groove PVC panel is an extruded poly vinyl chloride (PVC) cladding conforming to the requirements of ASTM D3676 with a PVC film laminated to the exterior surface of the panels. Panels are formed with an upper edge having nail slots and a lower edge that stacks into the upper edge of the lower course. The cladding is available in a range of colors.

1.4 Qualifications

ICC NTA in Bryan, TX has demonstrated compliance with ISO/IEC 17025 and is consequently accredited as a Testing Laboratory. ICC NTA is accredited to perform all testing reported herein.

1.5 Product Sampling

ChamClad, 6-in. wide, V-groove PVC Exterior Panels were sampled by ICC NTA, LLC personnel for the testing reported herein. The specimen(s) were randomly selected from overstock material at the manufacturing warehouse (On-Site) and tagged prior to shipment with appropriate sample marking identification, (Reference ICC NTA, LLC Information Gathering and Sample Submission Form, Project No: CWaL032323-51 dated 04/27/2023). All test specimens were supplied by ChamClad. Specimens arrived at ICC NTA, LLC facility in Bryan, Texas on 05/26/2023.

1.6 Witnessing

The following were present for testing reported herein via video conference call:

Witness	Organization
Sami Sakalla	ChamClad
Amber Gunderson	ChamClad
Tony Crimi	A.C. Consulting Solutions Inc.

1.7 Conditions of Testing

Unless otherwise indicated, all testing reported herein was conducted in ambient laboratory conditions.

2.0 Referenced Standards

ASTM E119-22, Standard Test Methods for Fire Tests of Building Construction and Materials

ASTM E2226-15b, Standard Practice for Application of Hose Stream

CAN/ULC-S101-14, Standard Methods of Fire Endurance Tests of Building Construction and Materials

3.0 Summary of Results

**Fire Resistance Rating: 120 minutes
Hose Stream: Pass
Non-Loadbearing Assembly**

4.0 ASTM E119-22 (CAN/ULC-S101-14)

4.1 General

4.1.1 Fire Endurance Test

The fire exposure is continued on the specimen with its applied load, if applicable, until failure occurs, or until the specimen has withstood the test conditions for the desired fire endurance rating.

4.1.2 Test Furnace

The test furnace is designed to allow the test specimen to uniformly be exposed to the specified time-temperature conditions. It is fitted with six (6) natural gas/air burners positioned on the left and right-side walls, designed to provide an even heat flux distribution across the face of the test specimen while inhibiting direct flame introduction. Each burner can produce a maximum of 1.5 MBtu/hr. The test engineer has overall control of the furnace in order to vary the following variables during the test: the overall energy input into the furnace, the air: gas ratio to the burners, and the input of additional air beyond that passing through the burners. The furnace opening is 14 ft. wide by 12 ft. tall by 4 ft. deep. The furnace can be equipped with a concrete adapter in order to reduce the opening for testing of a 10 feet x 10 feet wall, if desired. Furnace pressure may be maintained at a predetermined value based on the laboratory ambient pressure.

The temperature within the furnace is determined to be the mathematical average of thermocouples located symmetrically within the furnace and positioned six (6) inches away from the vertical face of the test specimen. The construction of these thermocouples is per ASTM E119. During the test, the furnace temperatures are recorded and displayed every 15 seconds to allow for the test engineer to control the energy input and follow the specified time-temperature curve. The data is saved every minute for report purposes.

The furnace interior temperature during a test is controlled such that the corresponding area under the time-temperature curve is within 10% of the corresponding area under the standard time-temperature curve for one (1) hour or less tests, 7.5% for tests longer than 1 hour, but less than two (2) hours, and 5% for tests longer than two (2) hours.

The fire exposure is controlled in order to follow the standard time-temperature curve, see Figure No. 1 in Appendix B - Data.

4.1.3 Temperatures of Unexposed Surfaces

Temperatures of the unexposed face are monitored using 18-gauge or lighter gauge, Type K thermocouples placed under 6-inch x 6-inch x 0.4-inch-thick, dry felted pads as described in the standard. Temperature readings are taken at not less than nine points on the surface, at intervals not exceeding one minute. The temperature on the unexposed surface is to be taken as the average value of all thermocouples, unless noted otherwise. Transmission of heat through the test assembly during the fire-resistance period shall not raise the temperature on the unexposed face more than 250° F above its initial average temperature at the start of the test or 325°F above its initial temperature at any single point. One thermocouple is located approximately at the center of the wall and four others are placed approximately in the center of each quarter of the wall. The remaining four are symmetrically located on the unexposed face to record the representative temperatures of the unexposed face. Thermocouples were located no closer than 3 in. to a panel joint or fastener head. For thermocouple locations on the unexposed face, see Appendix D – Drawings and graphical representation within Appendix B – Data.

4.1.4 Hose Stream Test

If required, this practice is intended to standardize the apparatus and method used to represent a standard hose stream to building elements as part of the assessment and fire resistance of building products. This practice specifies the water pressure and duration of application of the hose stream to the test assembly. This practice is to be used only after a test assembly has completed a prescribed standard fire-resistance test. The practice exposes a test assembly to a standard hose stream under controlled laboratory conditions. The apparatus used to apply the hose stream is built per ASTM E2226 with a 2-1/2 in. diameter hose to a playpipe with a 1-1/8 in. discharge tip that delivers a solid stream of water. Hose stream application time and water pressure varies based on the intended fire resistance period and is noted within ASTM E2226. The nozzle tip is located 20 feet away from the test assembly and verified prior to applying the hose stream to the test assembly. The hose stream starts at one corner of the test assembly and the stream is directed to the entire face of the test assembly. The hose stream follows the pattern provided in the standard. A fully developed hose stream shall not pass through the unexposed face of the test assembly. Alternatively, a duplicate wall assembly shall be exposed to a standard time-temperature curve for one-half the duration of the initial fire-resistance test prior to be subjected to the rapid cooling and erosional effects of the standard hose stream application.

4.1.5 Furnace Pressure

In accordance with CAN/ULC-S101, the pressure differential between the exposed and unexposed surfaces of the test assembly shall be measured. The pressure shall be measured by a minimum of two pipe probes constructed per the standard. Control of the furnace pressure shall be established no later than 10 minutes after the start of the test and shall be maintained for the remainder of the fire resistance duration. The two probes are separated by a vertical distance of at least 6-ft. The location of the neutral pressure plane shall be calculated based on the vertical separation of the two pressure sensing probes. All pressure measurements are taken at intervals not exceeding one minute. Furnace Pressure was not monitored during testing. No requirement for location of neutral pressure plane is specified within CAN/ULC-S101.

4.1.6 Correction Factor

When the indicated resistance period is 1/2 h or over, and the wall assembly exceeds acceptance criteria limitations, determined by the average or maximum temperature rise on the unexposed surface or within the test specimen, or by failure under load, a correction shall be applied for variation of the furnace exposure from that prescribed, where it will affect the classification.

The correction factor can be expressed as follows:

$$C = \frac{2I(A - A_S)}{3(A_S + L)}$$

Where:

C = time correction in the same units as I

I = indicated fire resistance in minutes

A = area under the curve of indicated average furnace temperature for the first three fourths of the indicated period

A_S = area under the standard furnace temperature curve for the same part of the indicated period, and L = lag correction in the same units as A and A_S ($54^{\circ}\text{F}\cdot\text{h}$ or $30^{\circ}\text{C}\cdot\text{h}$ ($3240^{\circ}\text{F}\cdot\text{min}$ or $1800^{\circ}\text{C}\cdot\text{min}$)).

5.0 Test Specimens

A representative test specimen was constructed and built under representative conditions of those applied in the field during construction in order to assess the materials, workmanship, and details such as dimensions of parts and all components in the assembly. ICC NTA, LLC lab personnel constructed the 10 ft. × 10 ft. wall assembly.

5.1 Framing

The framing of the wall assembly consisted of 3-5/8-in. deep, 20-gauge equivalent (20-ga. EQ.) steel studs, Clark Dietrich product: 362PDS125-18. The 20-ga. EQ. studs were spaced 16-in. on-center with 12-in. edge-to-center spacing on each end of the wall assembly. The studs were fastened to the top and bottom tracks, Clark Dietrich product: 362PDT125-18, 20-gauge equivalent C-shaped track, using #8 – 1/2 in. long, wafer head, self-drilling framing screws.

5.2 Interior Sheathing

The interior side of the wall assembly was sheathed using a double layer of 5/8-in. thick, Type X gypsum wallboard (GWB) conforming to ASTM C1396 directly attached to the steel studs. The base layer gypsum wallboard was secured to the studs using #6 – 1-in. long self-drilling, bugle head drywall screws. The fasteners were spaced 8 in. on-center around the perimeter and 12 in. on-center in the field of the panel. Fasteners around the perimeter of the GWB were spaced 3/8 in. from the edge of the panel. The 10 ft. long edge of the panels were oriented vertically. All seams were left exposed. The face layer of GWB was secured to the steel studs through the base layer GWB using #6 – 1-5/8-in. long self-drilling, bugle head drywall screws. Face layer GWB fasteners were offset a maximum of 4-in. to avoid aligning with base layer fasteners. The long dimension of the face layer GWB was oriented vertically and staggered a minimum of one stud cavity from the underlying vertical seams of the base layer GWB. The face layer GWB vertical seams were treated with a Level 2 finish consisting of nominal 2-in. wide paper seam tape embedded in joint compound and wiped with a joint knife leaving a thin layer of joint compound over the tape. All fasteners were covered with one coat of joint compound.

5.3 Exterior Sheathing

The exterior side of the wall assembly sheathing consisted of two layers of 5/8-in. thick, Type X GWB. The base layer consisted of 4x10-ft. panels of Type X, paper-faced GWB conforming to ASTM C1396. The base layer GWB was secured to the steel studs using #6 – 1-in. long self-drilling, bugle head drywall screws. The fasteners were spaced 8 in. on-center around the perimeter and 12 in. on-center in the field of the panel. Fasteners around the perimeter of the GWB were spaced 3/8 in. from the edge of the panel. The 10 ft. long edge of the panels were oriented vertically. The vertical, tapered edge seams were staggered a minimum of one stud cavity so to avoid aligning with vertical seams of base layer on exposed face of wall assembly. The face layer of Type X GWB consisted of USG™ SECUROCK® Brand Glass-Mat Sheathing conforming to ASTM C1177. The 4x8-ft. sheets of SECUROCK® were installed with the long dimension vertically oriented. The horizontal butt joints were staggered a minimum of 6-ft. on-center. The vertical tapered seams were staggered a minimum of one stud cavity from the underlying tapered seams of the base layer. No joint compound or seam tape was used on the exterior glass-mat sheathing.

5.4 Water Resistive Barrier

A water resistive barrier (WRB) consisting of DuPont™ Tyvek® CommercialWrap® D (ESR-2375) was installed over the exterior glass-mat sheathing on the exterior face of the wall assembly. The WRB was temporarily secured to the sheathing using T50, ½-in. crown staples. The WRB was installed per the manufacturer's specifications. Seams were overlapped a minimum of 6-in.

5.5 Exterior Furring Channels

Hat-shaped framing members used to "furr" out the ChamClad V-groove exterior panels were installed on the exterior face of the wall assembly over the WRB. The Clark Dietrich furring channels, product: 150F125-30, a 20-ga. (30-mils thick) were secured to the steel studs through both layers of Type X GWB using #6 – 1-5/8-in. long, self-drilling screws with bugle head. The hat channels were spaced 16-in. on-center with only one leg secured to the studs. The fasteners were spaced 12-in. on-center vertically.

5.6 Exterior Cladding

The exterior cladding consisted of ChamClad 6-in. wide, V-groove PVC Exterior Panels (ESR-4560). The V-groove siding panels were secured to the hat channels using #8 – ¾-in. long, self-drilling screws with pan head spaced 16-in. on-center. Care was taken to ensure the V-groove siding panels locked into the previous course before securing in place with fasteners positioned in the center of the fastening slots located along the attachment flange of the panels.

6.0 Test Setup and Procedure (Interior Face Exposure)

The product(s) were setup and evaluated in accordance with the 2022 version of ASTM E119 (2014 version of CAN/ULC-S101). The non-loadbearing, non-symmetrical wall assembly was placed in front of the vertical furnace at ICC NTA, Inc.'s Fire Testing Laboratory with the GWB, interior sheathed face towards the furnace opening on 06/02/2023. The thermocouple leads were connected to the data acquisition system in the control room and the connection was verified prior to ignition. The ambient air temperature within the lab was 87°F, with a relative humidity of 53%.

Deviations from the standard include: No furnace pressure measurements were collected per CAN/ULC-S101.

6.1 Test Observations

At 12:16 PM on June 2nd, 20203, the burners were ignited, and the furnace temperature was controlled following the standard time-temperature curve for a target period of 120 minutes.

Time (hr:min:sec)	Observation
0:00	Burners Lit, Test Started
10:26	Paper facing of exposed face GWB calcifying
15:00	No change to unexposed face
19:42	Discoloration of fastener heads showing through joint compound on exposed face
26:33	Vertical cracks developing in face layer GWB on exposed face; parallel to tapered edge seams
27:30	Joint compound and paper seam tape beginning to delaminate on exposed face
30:00	No change to unexposed face
37:00	Joint compound and paper seam tape continuing to delaminate on exposed face
44:30	Both vertical tapered edge seams fully exposed; seams open approx. ¼-in. on exposed face
45:00	No change to unexposed face
1:00:00	Face layer GWB showing signs of buckling/ warping on exposed face of wall assembly
1:00:30	Top coarse of PVC siding panel warping at top right corner of assembly, venting steam
1:10:00	Vertical crack on exposed face increasing in length and opening slightly
1:15:00	Vertical tapered edge seams open approx. 3/4-in.
1:15:30	No change to unexposed face

Time (hr:min:sec)	Observation
1:30:00	No change to unexposed face or exposed face of wall assembly
1:37:30	Face layer GWB beginning to separate from base wall assembly on exposed face
1:45:00	No change to unexposed face
1:48:00	Increase separation of face layer GWB on exposed face; still intact
1:50:00	Face layer GWB on exposed face beginning to sag at top of wall assembly
1:56:00	Moisture beginning to weep at seams of PVC siding panels
1:57:33	Piece of face layer GWB fell from top of wall assembly on south side of wall assembly on exposed face
2:00:00	Fire-Resistance portion concluded. No temperature thresholds exceeded. No gaps or openings present through wall assembly

Hose Stream Application Observations

Time (hr:min:sec)	Observation
2:03:22	Wall assembly in position for hose stream application (30 psi for 150 seconds)
2:03:59	Hose stream application started
2:06:32 (153 secs.)	Hose stream application concluded. No projection of water observed beyond the unexposed surface of the wall assembly.

Post-Mortem Observations

Component	Observation
Interior Sheathing (Exposed Face)	Approx. 90% of face layer GWB remained intact through duration of fire resistance portion of test with full deterioration of both layers during hose stream application.
Exterior GWB (Unexposed Face)	Remained intact through full duration of fire resistance portion of test. Base layer deteriorated during hose stream test. Face layer, glass-mat sheathing remained mostly intact throughout duration of all testing, small blowout through sheathing during hose stream test
WRB	Slight discoloration and charring at top of wall assembly and at horizontal butt joints of glass mat sheathing
ChamClad, 6-in. wide V-groove PVC exterior panels	Remained intact throughout the full duration of all testing. Minimal wetting of unexposed face during hose stream portion due to some seeping at seams.

7.0 Test Setup and Procedure (Exterior Face Exposure)

The product(s) were setup and evaluated in accordance with the 2022 version of ASTM E119 (2014 version of CAN/ULC-S101). The non-loadbearing, non-symmetrical wall assembly was placed in front of the vertical furnace at ICC NTA, Inc.'s Fire Testing Laboratory with the ChamClad 6-in. wide, V-groove PVC Exterior Panels towards the furnace opening on 06/06/2023. The thermocouple leads were connected to the data acquisition system in the control room and the connection was verified prior to ignition. The ambient air temperature within the lab was 83°F, with a relative humidity of 62%.

Deviations from the standard include: No furnace pressure measurements were collected per CAN/ULC-S101.

7.1 Test Observations

At 1:36 PM on June 6th, 2023, the burners were ignited, and the furnace temperature was controlled following the standard time-temperature curve for a target period of 120 minutes.

Time (hr:min:sec)	Observation
0:00	Burners Lit, Test Started
1:00	Significant smoke escaping around perimeter of assembly and around moveable test frame on unexposed side
2:20	Smoke escaping around wall assembly on unexposed side fully dissipated
15:00	Limited visibility into furnace due to smoke and flaming on exposed face
15:00	No change to unexposed face of wall assembly
30:00	No change to exposed face; no visibility into furnace
30:00	No change to unexposed face
45:00	No change to unexposed face
45:30	Continued limited visibility into furnace
1:00:00	No change to unexposed face
1:10:30	Exterior PVC paneling completely burned/melted away from assembly on exposed face. Hat channel showing signs of warping/buckling
1:15:00	No change to unexposed face
1:20:40	Glass-mat sheathing seams beginning to open
1:30:00	No change to unexposed face
1:30:30	Little to no change to exposed face
1:40:10	Portion of glass-mat sheathing fell from between hat channels at center of assembly

Time (hr:min:sec)	Observation
1:45:00	No change to unexposed face. Wall assembly showing signs of slight deflection towards furnace
1:45:10	Vertical cracking developing in remaining glass-mat sheathing on exposed face
1:57:05	Increased separation of glass-mat sheathing on exposed face
2:00:00	Fire-Resistance portion concluded. No temperature thresholds exceeded. No gaps or openings present through wall assembly

Hose Stream Application Observations

Time (hr:min:sec)	Observation
2:02:38	Wall assembly in position for hose stream application (30 psi for 150 seconds)
2:03:00	Hose stream application started
2:04:07 (66 secs.)	Blowout of unexposed face, bottom left corner of assembly. Continued hose stream application
2:04:16 (76 secs.)	Hose stream application terminated

Post-Mortem Observations

Component	Observation
Exposed GWB	Approx. 90% of face layer GWB remained intact through duration of fire resistance portion of test with full deterioration of both layers during hose stream application.
Unexposed GWB	Remained intact through full duration of fire resistance portion of test. Base layer mostly deteriorated during hose stream test. Face layer, glass-mat sheathing remained mostly intact throughout duration of fire resistance portion of testing, blowout through sheathing during hose stream test
WRB	Fully burned away during fire resistance portion of testing.
ChamClad, 6-in. wide V-groove PVC exterior panels	Fully deteriorated during fire resistance portion of testing.

8.0 Hose Stream Retest Setup and Procedure (Exterior Face Exposure)

A duplicate wall assembly was constructed in order to assess the erosional and rapid cooling effects of a standard hose stream application to the wall assembly following a fire resistance period equal to half the duration of the initial fire resistance test. All components of the duplicate assembly matched that of the initial wall assembly. The non-loadbearing, asymmetrical wall assembly was placed in front of the vertical furnace at ICC NTA, Inc.'s Fire Testing Laboratory with the face of the wall assembly cladded with ChamClad 6-in. wide V-groove PVC Exterior Panels exposed to the furnace environment. The thermocouple leads were connected to the data acquisition system in the control room and the connection was verified prior to ignition. The ambient air temperature within the lab was 88°F, with a relative humidity of 70%.

At 1:28 PM on June 16, 2023, the burners were ignited, and the furnace temperature was controlled following the standard time-temperature curve for a target period of 60 minutes.

Time (hr:min:sec)	Observation
0:00	Burners Lit, Test Started
1:04	Significant smoke escaping perimeter of wall assembly and moveable test frame on unexposed side of specimen
1:49	Smoke dissipating
5:35	Cladding beginning to fall from assembly on exposed face
15:00	No change to unexposed face
20:44	Furnace filled with significant smoke and flames limiting visibility
26:05	All cladding has fallen from assembly on exposed face; exterior GWB fully exposed
30:00	No change to unexposed face
34:00	Horizontal butt joints of exterior GWB beginning to open. Approx. ½-in.
40:00	Limited visibility into furnace – no conclusive observations
45:00	No change to unexposed face
47:00	Little to no change to exposed face
1:00:00	Fire resistance portion concluded. Burners extinguished

Hose Stream Application Observations

Time (hr:min:sec)	Observation
1:02:15	Wall assembly in position for hose stream
1:02:50	Hose stream application started (30 psi for 150 seconds)
1:05:21 (151 secs.)	Hose stream application concluded. No projection of water beyond unexposed surface of wall assembly observed.

9.0 Summary and Conclusions

The asymmetrical, non-loadbearing wall assembly described in this report did meet the Conditions of Acceptance of ASTM E119 (CAN/ULC-S101) when both faces of the wall assembly were exposed to the standard time-temperature curve for a period 120 minutes across two tests. The unexposed temperatures of the wall assembly detailed within this report did not exceed the maximum temperature thresholds for the duration of each fire resistance period of 120 minutes. When exposed from the interior face of the wall assembly, a hose stream application in accordance with ASTM E2226 was performed on the assembly immediately following the furnace exposure per ASTM E119. No projection of water was observed beyond the unexposed surface of the wall assembly. When exposed from the exterior face of the wall assembly, a hose stream application in accordance with ASTM E2226 was performed on a duplicate assembly immediately following a furnace exposure equal to half the duration of the initial fire resistance period per ASTM E119. No projection of water was observed beyond the unexposed surface of the wall assembly. The wall assembly detailed within this report obtained a Fire Resistance Rating of 120 minutes from both the interior and exterior surface of the wall assembly cladded with ChamClad's 6-in. wide, V-groove PVC Exterior Panels installed on the exterior face of the assembly.

10.0 Closing Statement

This report contains only findings and results arrived at after employing the specific test procedures listed herein. It does not constitute a recommendation for, endorsement of, or certification of the product or material tested. Unless differently required, ICC NTA, LLC reports apply the "Simple Acceptance" rule, also called "Shared Risk approach", of ILAC-G8:09/2019, Guidelines on Decision Rules and Statements of Conformity. ICC NTA makes no warranty, expressed or implied, except that the test has been performed, and a report prepared, based upon the specimen specified by the client. Extrapolation of data, from the test data provided herein, to the batch or lot from which the specimens were obtained may not correlate and should be interpreted with extreme caution. ICC NTA assumes no responsibility for variations in quality, composition, appearance, performance, or other features of similar materials produced by the client, other persons, or under conditions over which ICC NTA has no control. ICC NTA has issued this report for the exclusive use of the client to whom it is addressed. Any use or duplication of this report shall not be made without their consent. This report shall only be reproduced in its entirety.
